IMPLEMENTING C++ CLASSES: ACCESS SPECIFIERS CONSTRUCTORS

Problem Solving with Computers-II

Read the syllabus. Know what's required. Know how to get help.

CLICKERS OUT – FREQUENCY AB

From last lecture...

- Last time we defined a class DayOfYear and wrote a main function that created objects of this class
- We did not implement the member functions of the class.
- When the code was compiled with g++, it resulted in a linker error but when we compiled with the -c option, compilation was successful. Why?
- A. The -c option suppresses linker errors and produces and executable
- B. The -c option does not attempt to link code and no executable is produced
- C. None of the above

```
In Java:
public class DayOfYear {
    public void setDate(int mon, int day){
        dd = day;
        mm = mon
    }
    private int dd;
    private int dd;
    private int mm;
}

C++, attempt 1:
class DayOfYear {
    public void setDate(int mon, int day);
    private int dd;
    private int mm;
}
```

3

Which of the following is a problem with the C++ implementation above?

- A. The implementation of the member function setDate should be included in the class
- B. The class DayOfYear should be declared public
- C. The semicolon at the end of the class will cause a compile error
- D. In C++ you specify public and private in regions, not on each variable or function

Which of the following is a problem with the C++ implementation?

- A. In definition of **setDate**, member variables mm and dd should be accessed via objects
- B. Objects declared outside the class cannot access the private member variables
- C. None of the above

```
C++, attempt 2:
class DayOfYear {
  public:
      void setDate(int mon, int day);
  private:
      int dd;
      int mm;
};
void DayOfYear::setDate(int mon, int day) {
      mm = mon;
      dd = day;
}
int main() {
    DayOfYear today;
    today.setDate(1, 9);
    cout<<"Today's date is: ";</pre>
    cout<< today.mm <<"/"<< today.dd;</pre>
    return 0;
}
```

```
5
                                           C++, attempt 3:
                                           class DayOfYear {
                                            public:
What will be printed by this code?
                                                 void setDate(int mon, int day);
                                                 int getMonth();
A 1/9
                                                 int getDay();
B. 1/1
                                             private:
C. 12/1
                                                 int dd;
D. Compiler error
                                                 int mm;
E. None of the above
                                           };
                                          void DayOfYear::setDate(int mon, int day)
                                                mm = mon;
                                                dd = day;
                                           }
int main() {
                                           int DayOfYear::getMonth() {
    DayOfYear today;
                                                dd = 1;
    today.setDate(1, 9);
                                                return mm;
    cout<<"Today's date is: ";</pre>
                                           }
    cout<< today.getMonth() <<"/"</pre>
                                           int DayOfYear::getDay() {
        << today.getDay();
                                                mm = 12;
    return 0;
                                                return dd;
}
                                           }
```

How can we make sure that a function doesn't inadvertently change the member variables of the class?

A. Declare the variables const (as shown)B. Declare the function as a const

```
int main() {
   DayOfYear today;
   today.setDate(1, 9);
   cout<<"Today's date is: ";
   cout<< today.getMonth() <<"/"
        << today.getDay();</pre>
```

}

```
6
C++, attempt 4:
class DayOfYear {
  public:
      void setDate(int mon, int day);
      int getMonth();
      Int getDay();
  private:
      const int dd;
      const int mm;
};
void DayOfYear::setDate(int mon, int day)
     mm = mon;
     dd = day;
}
int DayOfYear::getMonth() {
     dd = 1;
     return mm;
int DayOfYear::getDay() {
     mm = 12;
     return dd;
}
```

How can we make sure that a function doesn't inadvertently change the member variables of the class?

```
Declare the function as a const
```

Introduce new terms:

- Accessors (getters)
- Mutators (setters)

}

```
int main() {
   DayOfYear today;
   today.setDate(1, 9);
   cout<<"Today's date is: ";
   cout<< today.getMonth() <<"/"
        << today.getDay();</pre>
```

```
C++, attempt 5: this version is correct!!!
class DayOfYear {
  public:
      void setDate(int mon, int day);
      int getMonth()const;
      int getDay()const;
  private:
      int dd;
      int mm;
};
void DayOfYear::setDate(int mon, int day)
     mm = mon;
     dd = day;
int DayOfYear::getMonth() const{
     return mm;
int DayOfYear::getDay() const{
     return dd;
}
```

```
• What is the output of this code?
```

```
int main() {
   DayOfYear today;
   // today.setDate(1, 9);
   cout<<"Today's date is: ";
   cout<< today.getMonth() <<"/"
        << today.getDay();</pre>
```

}

```
C++, attempt 5: this version is correct!!!
class DayOfYear {
  public:
      void setDate(int mon, int day);
      int getMonth()const;
      int getDay()const;
  private:
      int dd;
      int mm;
};
void DayOfYear::setDate(int mon, int day)
     mm = mon;
     dd = day;
}
int DayOfYear::getMonth() const{
     return mm;
int DayOfYear::getDay() const{
     return dd;
}
```

Constructor

```
Constructor: An "initialization" function that
is guaranteed to be called when an object of
the class is created
```

```
* If you don't explicitly write a constructor, C++
will generate a default one for you
```

* Member variables are initialized to junk values

```
9
C++, attempt 5: We'll now try to improve this
class DayOfYear {
  public:
      void setDate(int mon, int day);
      int getMonth()const;
      int getDay()const;
  private:
      int dd;
      int mm;
};
void DayOfYear::setDate(int mon, int day
     mm = mon;
     dd = day;
int DayOfYear::getMonth() const{
     return mm;
int DayOfYear::getDay() const{
     return dd;
```

Constructor: Writing your own

- Constructors must have the same name as the class
- Constructors don't have a return type
- Different types of constructors
 - 1. Constructor with no parameters (default)
 - 2. Constructor with parameters (parameterized constructor)
 - 3. Constructor with parameters that have default values

```
int main() {
    DayOfYear today;
    //today.setDate(1, 9);
```

}

```
cout<<"Today's date is: ";
cout<< today.getMonth() <<"/"</pre>
```

<< today.getDay();

```
C++, attempt 6:
class DayOfYear {
```

public:

```
void setDate(int mon, int day);
int getMonth()const;
int getDay()const;
```

10

```
private:
    int dd;
    int mm;
};
```

//Function definitions omitted

```
C++, attempt 7:
                                        class DayOfYear {
Parametrized Constructor
                                          public:
                                              void setDate(int mon, int day);
                                               int getMonth()const;
                                               int getDay()const;
                                          private:
                                              int dd;
                                               int mm;
                                        };
int main() {
    DayOfYear today;
    //today.setDate(1, 9);
    cout<<"Today's date is: ";</pre>
    cout<< today.getMonth() <<"/"</pre>
        << today.getDay();
                                        //Function definitions omitted
}
```

11

```
C++, attempt 7:
                                          class DayOfYear {
Parametrized Constructor
                                             public:
                                                 void setDate(int mon, int day);
What is the output of this code?
                                                 int getMonth()const;
A. Compiler error
                                                 int getDay()const;
B. Junk values (default constructor is called)
                                                 DayOfYear(int mon, int day);
                                             private:
                                                 int dd;
                                                 int mm;
                                          };
                                          DayOfYear()::DayOfYear(int mon, int day)
                                           {
int main() {
                                                 mm = mon;
    DayOfYear today;
                                                 dd = day;
    cout<<"Today's date is: ";</pre>
                                           }
    cout<< today.getMonth() <<"/"</pre>
        << today.getDay();
}
                                          //Function definitions omitted
```

12

Parametrized Constructor with default parameters

In the declaration of the parameterized constructor, specify default values for the parameters

Objects can be created in all the following ways:

```
DayOfYear today;
DayOfYear today(1,8);
DayOfYear today(2);
```

}

```
int main() {
   DayOfYear today;
   cout<<"Today's date is: ";
   cout<< today.getMonth() <<"/"
        << today.getDay();</pre>
```

```
13
C++, attempt 8:
class DayOfYear {
  public:
      void setDate(int mon, int day);
      int getMonth()const;
      int getDay()const;
      DayOfYear(int mon=1,int day=1);
  private:
      int dd;
      int mm;
};
DayOfYear()::DayOfYear(int mon, int day)
{
      mm = mon;
      dd = day;
}
```

//Function definitions omitted

Summary

- Classes have member variables and member functions (method). An object is a variable where the data type is a class.
- You should know how to declare a new class type, how to implement its member functions, how to use the class type.
- Frequently, the member functions of an class type place information in the member variables, or use information that's already in the member variables.
- Constructors are used to initialized objects
- In the future we will see more features of OOP.

Next time

• The big four and operator overloading
