DYNAMIC MEMORY

Problem Solving with Computers-I

C++

```
#include <iostream>
using namespace std;

int main(){
    cout<<"Hola Facebook\n";
    return 0;
}
```

Learning Goals

- Understand pointer mechanics and how they are used to pass parameters to functions
- Creating data on the heap with new and delete
- Difference between data on the heap vs. data on the stack
- Functions returning pointers

Tracing code involving pointers

```
int* p;  
int x = 10;  
p = &x;  
*p = *p + 1;
```

$x = x + 1;$

Q: Which of the following pointer diagrams best represents the outcome of the above code?

$*p = *p + 1;$
 $x = x + 1;$

C. Neither, the code is incorrect

Pointer assignment

```
int* p1, *p2, x;
p1 = &x;
p2 = p1;
```

Handwritten notes:
x = 10
x = 3;
y = x;

Q: Which of the following pointer diagrams best represents the outcome of the above code?

A.

B.

```
int x;
int *p1 = &x;
int **p2 = &p1;
```

C. Neither, the code is incorrect

strings and c-strings: What is the output?

```
int main(int argc, char const *argv[])
{
    string manu = "Lamborghini";
    const char* c_manu = manu.c_str();

    string new_manu(manu);
    manu[0] = 'P';

    cout<< c_manu<<endl;
    cout<< new_manu<<endl;

    return 0;
}
```

int arr[3] = {1, 2, 3};

arr

1	2	3
---	---	---

0x8000 0 1 2

cout<< arr; // 0x8000

char c[4] = "ape";

c

'a'	'p'	'e'	'\0'
-----	-----	-----	------

0 1 2 3

cout<< c;

string a = "ape";

```

int main(int argc, char const *argv[])
{
    string manu = "Lamborghini";
    const char* c_manu = manu.c_str();

    string new_manu(manu);
    manu[0] = 'P';

    cout<< c_manu<<endl;
    cout<< new_manu<<endl;

    return 0;
}

```

copy constructor

string manu = "Lamborghini";
"Heap"

c_manu is a pointer to

new_manu

← copy

Constant pointers and pointers to constants

```
const char* p1;  
char* const p2;  
const char* const p3;
```

What is the difference between these declarations?

$p1 \rightarrow$ [a p e]
 ~~$p1 = 'b';$~~ X

$p2 \rightarrow$ [apple]
 $p2 = p1;$ X

```
void IncrementPtr(int* p){
    p++; // p = p + 1;
}
```

main() {

```
int arr[3] = {50, 60, 70};
```

```
int* q = arr;
```

```
IncrementPtr(q);
```

}

int x = 10;

int* p = &x;

arr

Which of the following is true after **IncrementPtr(q)** is called in the above code:

A. 'q' points to the next element in the array with value 60

B. 'q' points to the first element in the array with value 50

q is passed by value

arr[1]
*(arr + 1)

q = q + 1;
arr = arr + 1; // not arr + 1
0x8004

P 0x8004

pointer arithmetic

How should we implement `IncrementPtr()`, so that 'q' points to 60 when the following code executes? *p is a pointer to (int*)*

```
void IncrementPtr(int** p){  
    p++;  
}
```

```
int arr[3] = {50, 60, 70};  
int* q = arr;  
IncrementPtr(&q);
```

- A. `p = p + 1;`
B. `&p = &p + 1;`
C. `*p = *p + 1;`
D. `p = &p + 1;`

Passing the address of q to p translates to the following assignment
 $p = \&q;$

Since p is storing the address of an (int) it must be a pointer to a (int*) type.*

*That's why p is a double pointer
`int** p;`
p stores the address of a pointer to an int*

q = q + 1

Pointer pitfalls

- Dereferencing a pointer that does not point to anything results in undefined behavior.
- On most occasions your program will crash
- Segmentation faults: Program crashes because code tried to access memory location that either doesn't exist or you don't have access to

Two important facts about Pointers

- 1) A pointer can only point to one type –(basic or derived) such as `int`, `char`, a `struct`, another pointer, etc
- 2) After declaring a pointer: `int *ptr;`
`ptr` doesn't actually point to anything yet.
We can either:
 - make it point to something that already exists, OR
 - allocate room in memory for something new that it will point to

Pointer Arithmetic

- What if we have an array of large structs (objects)?
 - C++ takes care of it: In reality, `ptr+1` doesn't add 1 to the memory address, but rather adds the size of the array element.
 - C++ knows the size of the thing a pointer points to – every addition or subtraction moves that many bytes: 1 byte for a char, 4 bytes for an int, etc.

C++ Memory Model: Stack

- Stack: Segment of memory managed automatically using a Last in First Out (LIFO) principle
- Think of it like a stack of books!

C++ Memory Model: Heap

- Heap: Segment of memory managed by the programmer
- Data created on the heap stays there
 - FOREVER or
 - until the programmer explicitly deletes it

Creating data on the Heap: new

To **allocate** memory on the heap use the **new** operator

Deleting data on the Heap: delete

To **free** memory on the heap use the **delete** operator

Dynamic memory management = Managing data on the heap

```
int* p= new int; //creates a new integer on the  
heap
```

```
SuperHero* n = new SuperHero;
```

```
                //creates a new Student on the  
heap
```

```
delete p; //Frees the integer
```

```
delete n; //Frees the Student
```

The case of the disappearing data!

```
int getInt(){
    int x=5;
    return x;
}
int* getAddressOfInt(){
    int x=10;
    return &x;
}
int main(){
    int y=0, *p=nullptr, z=0;
    y = getInt();
    p = getAddressOfInt();
    z = *p;
    cout<<y<<" , "<<z<<" , "<<*p<<endl;
}
```

What is the output?

A. 5, 0, 10

B. 5, 10, 10

C. Something else

Heap vs. stack

```
1 #include <iostream>
2 using namespace std;
3
4 int* createIntArray(int len){
5
6     int arr[len];
7     return arr;
8
9 }
```

Does the above function correctly return an array of integers?

- A. Yes
- B. No
