

HEAPS

Problem Solving with Computers-II

C++

```
#include <iostream>
using namespace std;

int main(){
    cout<<"Hola Facebook!n";
    return 0;
}
```

GitHub

Heaps

- Clarification
 - *heap*, the data structure is not related to *heap*, the region of memory
- What are the operations supported?
- What are the running times?

Heaps as binary trees

- Rooted binary tree that is as complete as possible
- In a **min-Heap**, each node satisfies the following **heap property**:
 $\text{key}(x) \leq \text{key}(\text{children of } x)$

Min Heap with 9 nodes

Where is the minimum element?

Heaps as binary trees

- Rooted binary tree that is as complete as possible
- In a max-Heap, each node satisfies the following **heap property**:
 $\text{key}(x) \geq \text{key}(\text{children of } x)$

Max Heap with 9 nodes

Where is the maximum element?

Structure: Complete binary tree

A heap is a complete binary tree: Each level is as full as possible. Nodes on the bottom level are placed as far left as possible

Identifying heaps

Starting with the following min-Heap which of the following operations will result in something that is NOT a min Heap

- A. Swap the nodes 40 and 32
- B. Swap the nodes 32 and 43
- C. Swap the nodes 43 and 40
- D. Insert 50 as the left child of 45
- E. C&D

Insert 50 into a min-heap

- Insert key(x) in the first open slot at the last level of tree (going from left to right)
- If the heap property is not violated - Done
- Else: while($\text{key}(\text{parent}(x)) > \text{key}(x)$) swap the key(x) with key(parent(x))

Insert 50, then 35, then 8

Delete min

- Replace the root with the rightmost node at the last level
- “Bubble down”- swap node with child with the smallest key value until the heap property is restored

Under the hood of heaps

- An efficient way of implementing heaps is using vectors
- Although we think of heaps as trees, the entire tree can be efficiently represented as a vector!!

Implementing heaps using an array or vector

Value										
Index	0	1	2	3	4	5	6	7	8	9

Using vector as the internal data structure of the heap has some advantages:

- **More space efficient than trees**
- **Easier to insert nodes into the heap**

Finding the “parent” of a “node” in the vector representation

For a key at index i , index of the parent is $(i-1)/2$

Value	6	10	12	40	32	43	47	45	41	
Index	0	1	2	3	4	5	6	7	8	

Insert into a heap

- Insert key(x) in the first open slot at the last level of tree (going from left to right)
- If the heap property is not violated - Done
- Else....

Insert the elements {12, 41, 47, 45, 32} in a min-Heap using the vector representation of the heap

Insert 50, then 35

For a node at index i , index of the parent is $(i-1)/2$

Value	6	10	12	40	32	43	47	45	41	
Index	0	1	2	3	4	5	6	7	8	

Traversing down the tree

Value	6	10	12	40	32	43	47	45	41	
Index	0	1	2	3	4	5	6	7	8	

For a node at index i , what is the index of the left and right children?

- A. $(2*i, 2*i+1)$
- B. $(2*i+1, 2*i+2)$
- C. $(\log(i), \log(i)+1)$
- D. None of the above

Delete min

- Replace the root with the rightmost node at the last level
- “Bubble down”- swap node with one of the children until the heap property is restored

Delete min (pop)

Value	6	10	12	40	32	43	47	45	41	50	35
Index	0	1	2	3	4	5	6	7	8	9	10

What is the resulting vector after doing a pop()?
