# **BINARY SEARCH TREES**

Problem Solving with Computers-II

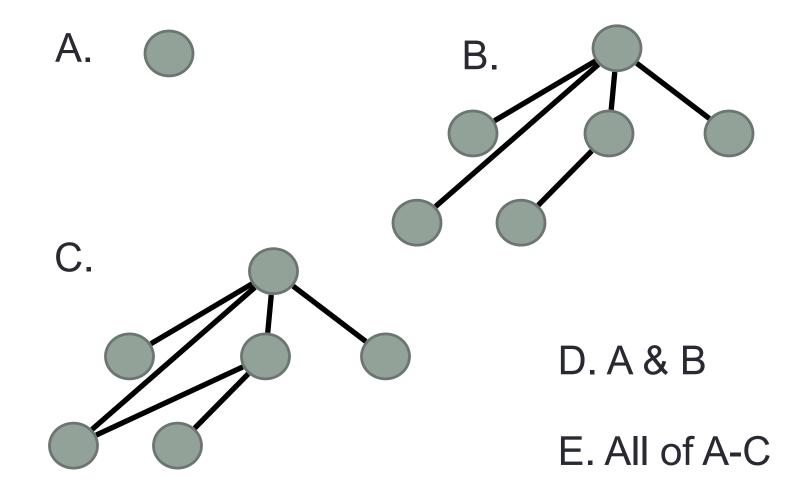

A tree has following general properties:

- One node is distinguished as a **root**;
- Every node (exclude a root) is connected by a directed edge *from* exactly one other node;
  - A direction is: *parent -> children*
- Leaf node: Node that has no children

Which of the following is/are a tree?

#### **Binary Search Trees**

• What are the operations supported?

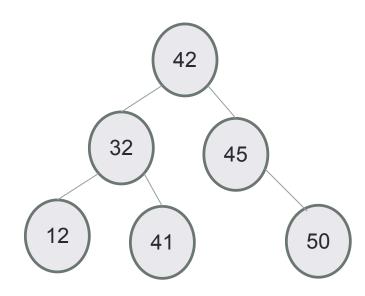

• What are the running times of these operations?

• How do you implement the BST i.e. operations supported by it?

#### Operations supported by Sorted arrays and Binary Search Trees (BST)

Operations	
Min	
Max	
Successor	
Predecessor	
Search	
Insert	
Delete	
Print elements in order	

#### Binary Search Tree – What is it?

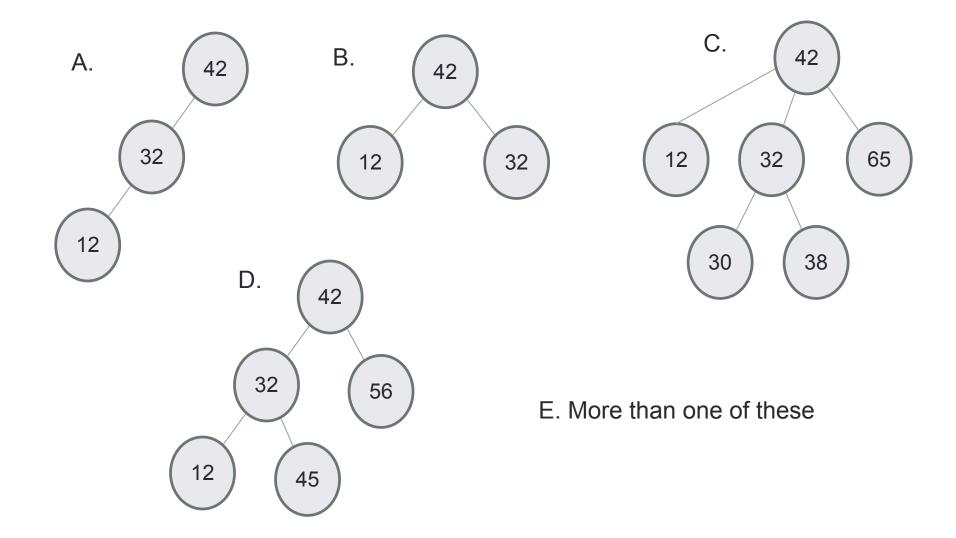

- Each node:
  - stores a key (k)
  - has a pointer to left child, right child and parent (optional)
  - Satisfies the Search Tree Property

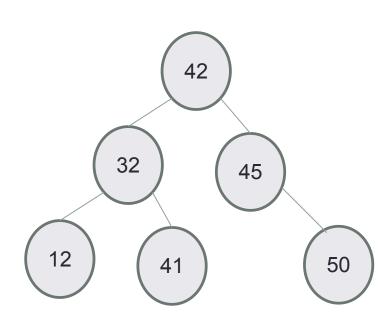

For any node,

Keys in node's left subtree < Node's key Node's key < Keys in node's right subtree

#### Which of the following is/are a binary search tree?

### BSTs allow efficient search!

- Start at the root;
- Trace down a path by comparing **k** with the key of the current node x:
  - If the keys are equal: we have found the key
  - If  $\mathbf{k} < \text{key}[\mathbf{x}]$  search in the left subtree of x
  - If **k** > key[x] search in the right subtree of x

Search for 41, then search for 53

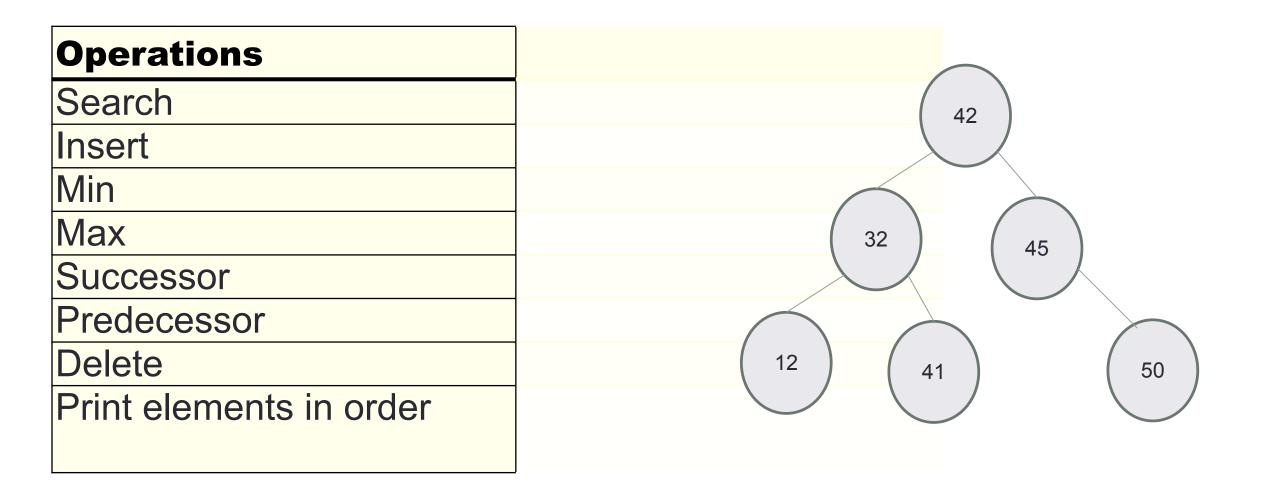

#### A node in a BST

class BSTNode {

public: BSTNode\* left; BSTNode\* right; BSTNode\* parent; int const data;

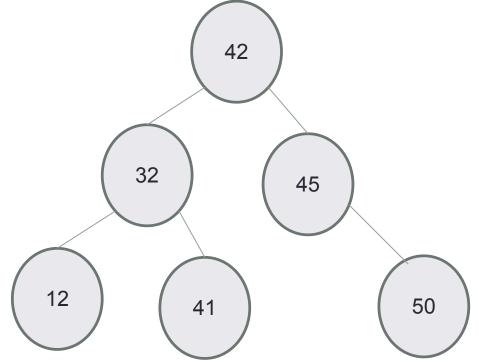

```
BSTNode( const int & d ) : data(d) {
    left = right = parent = 0;
};
```

### Define the BST ADT

### Traversing down the tree

- Suppose n is a pointer to the root. What is the output of the following code:
  - n = n -> left;
  - n = n->right;
  - cout<<n->data<<endl;</pre>
    - A. 42
    - B. 32
    - C. 12
    - D. 41
    - E. Segfault

### Traversing up the tree

- Suppose n is a pointer to the node with value 50.
- What is the output of the following code:

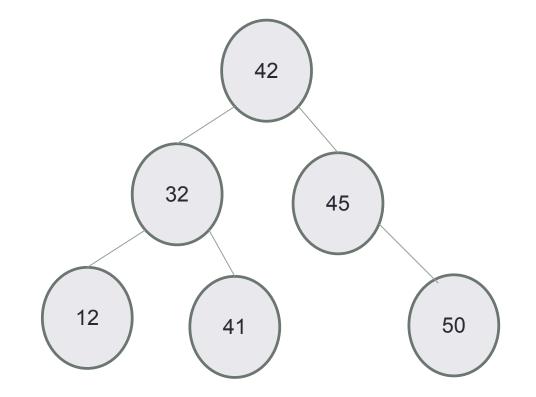

```
n = n->parent;
```

- n = n->parent;
- n = n->left;

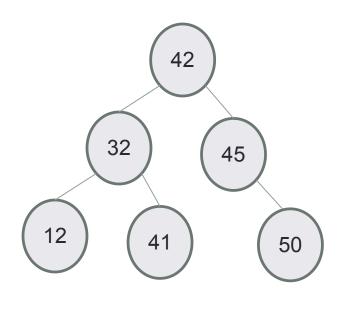

```
cout<<n->data<<endl;</pre>
```

- A. 42
- B. 32
- C. 12
- D. 45

E. Segfault

### Insert

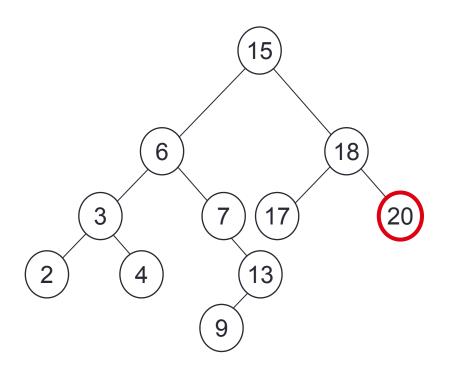

- Insert 40
- Search for the key
- Insert at the spot you expected to find it

#### Max

**Goal:** find the maximum key value in a BST Following right child pointers from the root, until a leaf node is encountered. The least node has the max value

Alg: int BST::max()

Maximum = 20

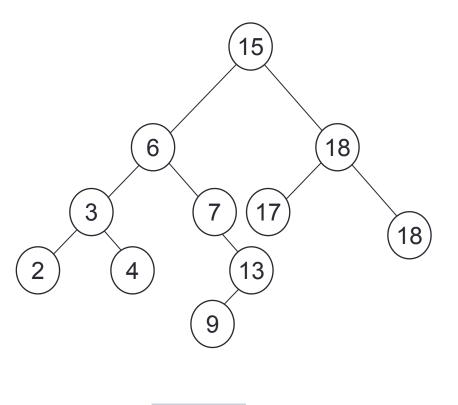

#### Min

**Goal**: find the minimum key value in a BST Start at the root.

Follow child pointers from the root, until a leaf node is encountered

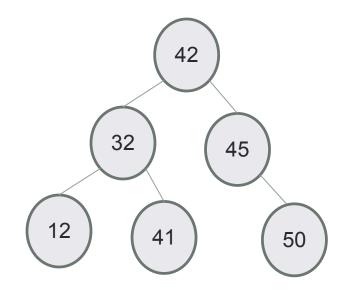

Leaf node has the min key value

```
Alg: int BST::min()
```

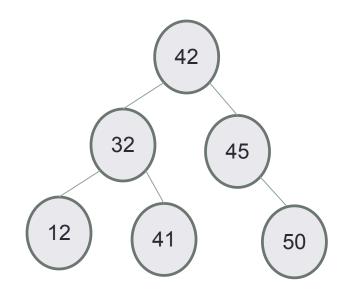

#### In order traversal: print elements in sorted order

Algorithm Inorder(tree)

- 1. Traverse the left subtree, i.e., call Inorder(left-subtree)
- 2. Visit the root.
- 3. Traverse the right subtree, i.e., call Inorder(right-subtree)

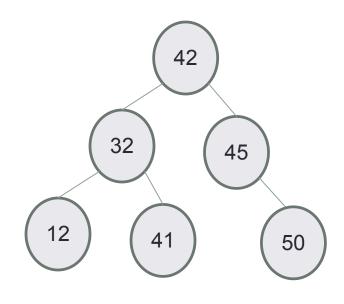

#### **Pre-order traversal: nice way to linearize your tree!**

Algorithm Preorder(tree)

- 1. Visit the root.
- 2. Traverse the left subtree, i.e., call Preorder(left-subtree)
- 3. Traverse the right subtree, i.e., call Preorder(right-subtree)

#### **Post-order traversal: use in recursive destructors!**

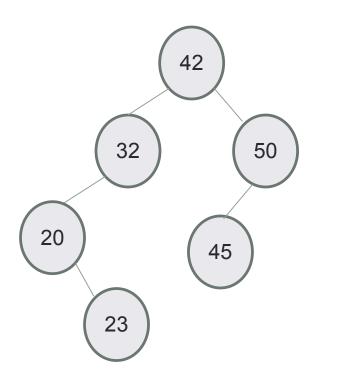

Algorithm Postorder(tree)

- 1. Traverse the left subtree, i.e., call Postorder(left-subtree)
- 2. Traverse the right subtree, i.e., call Postorder(right-subtree)

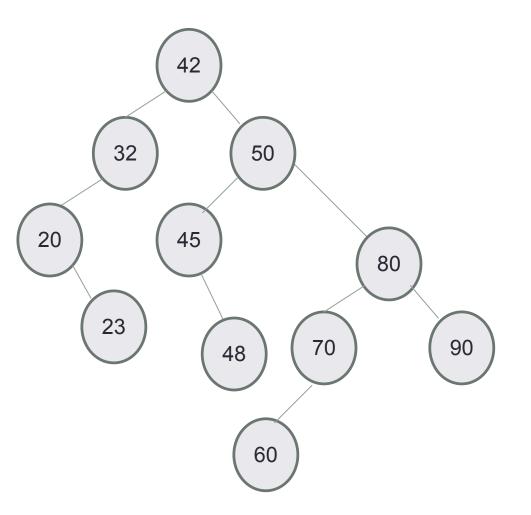

3. Visit the root.

# **Predecessor: Next smallest element**

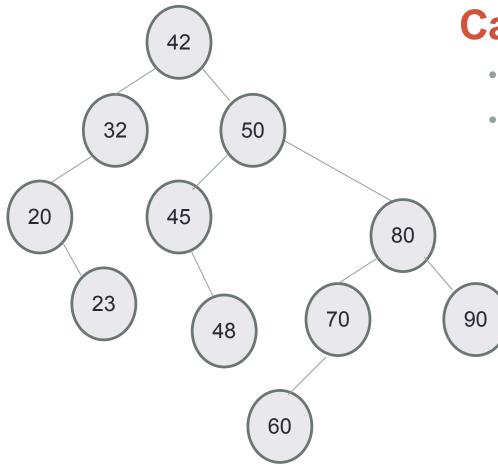

- What is the predecessor of 32?
- What is the predecessor of 45?

# Successor: Next largest element

- What is the successor of 45?
- What is the successor of 50?
- What is the successor of 60?

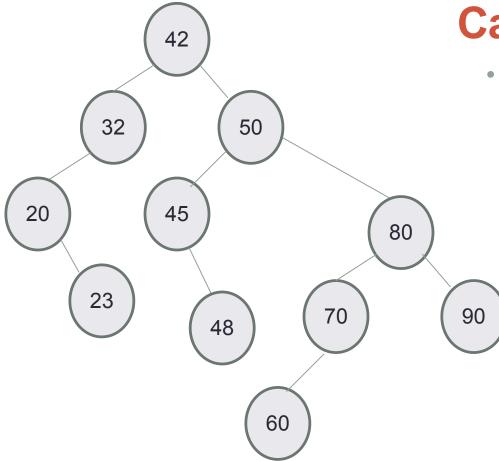

# **Delete: Case 1**

#### Case 1: Node is a leaf node

- Set parent's (left/right) child pointer to null
- Delete the node

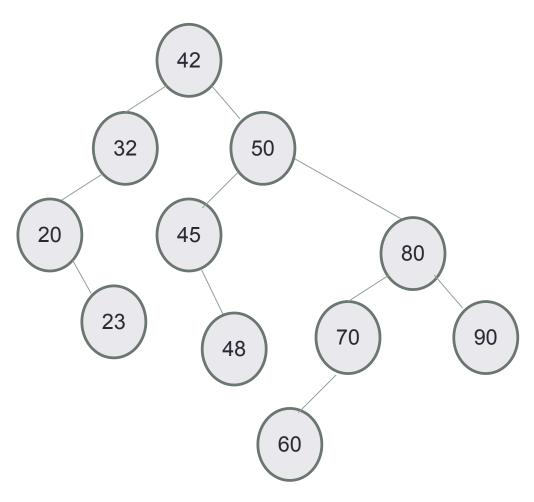

# **Delete: Case 2**

#### Case 2 Node has only one child

Replace the node by its only child

# **Delete: Case 3**

#### Case 3 Node has two children

• Can we still replace the node by one of its children? Why or Why not?

### **Binary Search**

- Binary search. Given value and sorted array a[], find index i such that a[i] = value, or report that no such index exists.
- Invariant. Algorithm maintains a[lo] ≤ value ≤ a[hi].
- Ex. Binary search for 33.

6	13	14	25	33	43	51	53	64	72	84	93	95	96	97
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
