

C++ OPERATOR OVERLOADING DESTRUCTOR

Problem Solving with Computers-II

The image shows the C++ logo in a blue, 3D-style font. Below the logo is a snippet of C++ code with syntax highlighting:

```
#include <iostream>
using namespace std;

int main(){
    cout<<"Hola Facebook\n";
    return 0;
}
```

Read the syllabus. Know what's required. Know how to get help.

x

2

y

4

$x + y$

$$2 + 4 = 6$$

"Hello"

"World!"

"Hello World!"

-1 + 2j

1 + 5j

Review Concepts from CS16

- Review basics of classes
 - Defining classes and declaring objects
 - Access specifiers: private, public
 - Different ways of initializing objects and when to use each:
 - Default constructor
 - Parametrized constructor
 - Parameterized constructor with default values
 - Initializer lists

Today's learning goals:

1. Operator overloading

- what is operator overloading?
- why/when would we need to overload operators?
- how to overload operators in C++ ?

2. Destructor:

- what is a destructor?
- why/when would we need one?
- how to implement a destructor?

How many objects of type Complex are created in main()?

```
int main(){
    Complex p;
    Complex *q = new Complex(2, 3);
    Complex w(10, -5);
    w.conjugate();
    w.print();
}
```

on the stack (pointing to `Complex p;`)
on the heap (pointing to `new Complex(2, 3);`)

```
class Complex
{
private:
    double real;
    double imag;
public:
    Complex(double re = 0, double im = 0);
    double getMagnitude() const;
    double getReal() const;
    double getImaginary() const;
    void print() const;
    void conjugate();
    void setReal(double r);
    void setImag(double r);
};
```

parameterized constructor (with arrow pointing to `Complex(double re = 0, double im = 0);`)

- A. One
- B. Two
- C. Three**
- D. Four
- E. I am not sure . . .

*Pointer diagram
on next page*

Constructor is not called when we
declare pointers to Complex

Complex *q;

This statement alone does not
call the constructor!

Fill in the blank to print the values of the object on the heap

```
int main(){  
    Complex p;  
    Complex *q = new Complex(2, 3);  
    Complex w(10, -5);  
    w.conjugate();  
    w.print();  
    q → print();  
} (*q). print();
```

Desired output:

10 + 5j
2 + 3j

Review Constructor

- The constructor is a special method that is called right AFTER an object is created in memory (on the heap or stack)
- The compiler automatically generates a default constructor
- But you can implement a user-defined version

New method: add()

```
int main(){
    Complex p;
    Complex *q = new Complex(2, 3);
    Complex w(10, -5);
    w.conjugate();
    p = add(*q, w);
    p.print();
}
```

Approach 1

non-member function of class
Complex

```
int main(){
    Complex p;
    Complex *q = new Complex(2, 3);
    Complex w(10, -5);
    w.conjugate();
    p = q -> add(w);
    p.print()
}
```

Approach 2

Member function of
Complex

New method: add()

```
int main(){
    Complex p;
    Complex *q = new Complex(2, 3);
    Complex w(10, -5);
    w.conjugate();
    p = add(*q, w);
    p.print();
}
```

A: Approach 1 : non-member

Complex add (const Complex & x,
const Complex & y);

```
int main(){
    Complex p;
    Complex *q = new Complex(2, 3);
    Complex w(10, -5);
    w.conjugate();
    p = q->add(w);
    p.print();
}
```

B: Approach 2 member

Complex add (const
Complex & x);

Overloading the + operator for Complex objects

```
p = add(x, w);
```

```
p = x.add(w);
```

$p = \text{Operator} + (x, w);$

$p = x \cdot \text{Operator} + (w);$

```
p = x + w;
```

Goal: We want to apply the + operator to Complex type objects

Overloading the << operator

```
int main(){  
    Complex p;  
    Complex *q = new Complex(2, 3);  
    Complex w(10, -5);  
    w.conjugate();  
    w.print();  
    q->print();  
}
```

Before overloading the << operator

```
int main(){  
    Complex p;  
    Complex *q = new Complex(2, 3);  
    Complex w(10, -5);  
    w.conjugate();  
    cout << w;  
    cout << *q;  
}
```

After overloading the << operator

OStream

```
cout << w;
```

Select any equivalent C++ statement:

```
w.operator<<(cout);
```

```
cout.operator<<(w);
```

```
operator<<(cout, w);
```

Order matters!

$b \ll a;$ \downarrow $b.operator\ll(a)$	$a \ll b;$ \downarrow $a.operator\ll(b)$
--	--

A (not A because order matters!)

(B) ✓

(C) ✓

```
operator<<(cout, w);
```

Select the function declaration that best matches the above call

A `void operator<<(ostream &out,
const Complex &c);`

B `void Complex::operator<<(ostream &out);`

C `Complex operator<<(ostream &out, Complex c);`

↑ but this return type can be problematic!

```
Complex w(1, 10), x(5, 1);  
cout<< w << x;
```

Select the function declaration that best matches the above call

A

```
void operator<<(ostream &out,  
                const Complex &c);
```

B

```
Complex& operator<<(ostream &out,  
                   const Complex &c);
```

C

```
ostream& operator<<(ostream &out,  
                   const Complex &c);
```

Operator Overloading

We would like to be able to perform operations on two objects of the class using the following operators:

<<

==

!=

+

-

and possibly others

Constant pointers and pointers to constants

```
const char* p1;  
char* const p2;  
const char* const p3;
```

Constructor and Destructor

Every class has the following special methods:

- Constructor: Called right AFTER an object is created in memory
- Destructor: Called right BEFORE an object is deleted from memory

The compiler automatically generates default versions, but you can provide user-defined implementations

next lecture!

```
void foo(){  
    Complex p(1, 2);  
    Complex *q = new Complex(3, 4);  
}
```

What is the output?

A. $1 + 2j$

B. $3 + 4j$

C. $1 + 2j$
 $3 + 4j$

D. None of the above

```
class Complex  
{  
private:  
    double real;  
    double imag;  
public:  
    Complex(double re = 0, double im = 0);  
    ~Complex(){ print();}  
    double getMagnitude() const;  
    double getReal() const;  
    double getImaginary() const;  
    void print() const;  
    void conjugate();  
    void setReal(double r);  
    void setImag(double r);  
};
```

Summary

- Classes have member variables and member functions (method). An object is a variable where the data type is a class.
- You should know how to declare a new class type, how to implement its member functions, how to use the class type.
- Frequently, the member functions of an class type place information in the member variables, or use information that's already in the member variables.
- New functionality may be added using non-member functions, friend functions, and operator overloading
- If a class allocates data on the heap, then a user-defined destructor must be implemented to perform a clean-up procedure (de-allocate heap memory)
